

CogniBase for Boston University

The OnBase domain layer for your data & AI engineering teams

Quiddity Innovations — draft brief (internal; becomes external when you choose to engage)

The problem. BU runs Hyland OnBase across thousands of tables with no enforced foreign keys, cryptic names (`hsi.itemdata`), and configuration locked inside `.expk` packages. A team can build REST plumbing against the Hyland API quickly — but knowing *where the checks live, how AP invoices link to vendors, and which keyword types matter for which process* takes deep OnBase domain experience. That domain layer is the hard part.

What CogniBase is. A vendor-neutral, local-first OnBase intelligence tool that combines:

- **Schema map** — full OnBase schema (live via Unity/REST or from `.expk`), with inferred relationships (a prior run produced 34 manual-derived + 6,167 inferred soft FKs).
- **Three-corpus RAG** — Operational Data / OnBase Configuration / Solution Documentation kept separate so PII never leaks into admin answers.
- **Query Federator** — joins across prefix-aliased keyword types (`AP\_Name` vs `HR\_Name`) that OnBase Custom Queries cannot.
- **Pluggable LLMs** — Claude, OpenAI, Gemini, or local Ollama; checkbox-active, zero hardcoded.
- **Compliance by construction** — five-layer access model, k-anonymity floor, Privacy Transformer, and an L1–L4 audit trail.

Why it fits BU's architecture (the price of entry — already met or in progress):

BU requirement	CogniBase
Open standards, MCP-native	RAG today; MCP tool wrapper in progress (natively callable by Nexus/Regent)
No per-seat, freedom to leave	Plain-file artefacts; open exit
Identity-aware & auditable (Entra ID)	L1–L4 audit today; Entra ID adapter planned
FERPA guardrails	Gates + Privacy Transformer; regulated data never leaves the box
Cloud-native / ARM / K8s	Docker today; ARM64 + Helm planned

How we'd work together. Coordinate, don't duplicate. Your REST POC team owns departmental DocType inventory and credentials; CogniBase brings the OnBase domain modelling, Normalizers, Gates, Query Federator, and the agent/RAG layer on top of the same Hyland API. Forward-deployed, lean, embedded.

The shape of a first step. One IT request issues credentials usable by both teams against a shared OnBase **test** instance. We demonstrate a real cross-DocType question answered via the Query Federator. No licence, no lock-in, pilot first.

Differentiation. This is the operational / IT-data / records domain — complementary to, not competing with, an admissions-focused frontier partner.
